Solutions should show all of your work, not just a single final answer.

1. The radius r of a spherical balloon is expanding at the rate of 14 in/min.
 - (a) Determine the rate at which the volume V changes with respect to time, in in^3/min , at the instant when $r = 8$ in. Round your answer to the nearest integer. Recall that $V = \frac{4}{3}\pi r^3$.
 - (b) Determine the rate at which the surface area S changes with respect to time, in in^2/min , when $r = 8$ in. Round your answer to the nearest integer. Recall that $S = 4\pi r^2$.
 - (c) If the radius doubles, does dV/dt double? Does dS/dt double?

2. Water is flowing into an upside-down right circular cone with height 3 m and radius 2 m at the top. As water fills the cone, let the height of the water in the cone be h m, and let r m be the radius of the surface of the water.
 - (a) Draw and label a diagram of this scenario, and find an expression for r in terms of h , then an expression for the volume V of water in the cone in terms of h alone (no r in the formula). Recall that the volume of a right-circular cone with height h and radius r is $\frac{1}{3}\pi r^2 h$.
 - (b) Express dV/dt in terms of h and dh/dt . If dV/dt is constant (and not zero), explain from your formula why dh/dt cannot be constant as well.
 - (c) Assuming the water flows into the cone at a constant rate of $2 \text{ m}^3/\text{min}$, how quickly is its height changing, in m/min , when the height is 2 m? Round your answer to the nearest tenth.

3. A cop sits in a parked car 10 feet off of a straight road. As you drive along the road, the cop trains a radar gun at your car. Let s be the distance from your car to the cop in feet. The radar gun measures the rate at which your distance from the police car is changing with respect to time, which is ds/dt . Let x be the distance, in feet, of your car from the point on the road that is closest to the cop, so your car's velocity is dx/dt .
 - (a) Draw and label a diagram of this scenario, and express dx/dt in terms of ds/dt , s , and x .
 - (b) Use part a to explain why $ds/dt < dx/dt$. Thus the radar gun's measurement of ds/dt always *underestimates* your car's velocity. (This is why if the radar gun measures a speed greater than the speed limit on the road, the car is going faster and thus deserves a ticket.)
 - (c) Does the conclusion in part (b) depend on the squad car being 10 feet, rather than some other (positive) distance, from the road?
