

Strategy to transform continuous random variables.

- Consider a random variable \mathbf{X} . Make sure you understand its p.d.f. $f_{\mathbf{X}}(x)$ and its c.d.f. $F_{\mathbf{X}}(x)$. These relations are important:

$$F'_{\mathbf{X}}(x) = f_{\mathbf{X}}(x)$$

$$F_{\mathbf{X}}(x) = \int_{-\infty}^x f_{\mathbf{X}}(t)dt = \mathbb{P}(\mathbf{X} < x)$$

$$F_{\mathbf{X}}(b) - F_{\mathbf{X}}(a) = \int_a^b f_{\mathbf{X}}(t)dt = \mathbb{P}(a < \mathbf{X} < b)$$

- Consider a function $g(x)$ and the transformed random variable $\mathbf{Y} = g(\mathbf{X})$. Denote $y = g(x)$, which *we can solve for* x , to obtain $x = g^{-1}(y)$.
- For now, assume that g is a *monotone increasing function*, and we understand the range of \mathbf{Y} .

$$\min(\mathbf{Y}) = g(\min(\mathbf{X})) \leq \mathbf{Y} \leq \max(\mathbf{Y}) = g(\max(\mathbf{X}))$$

- (1) The c.d.f. of \mathbf{Y} can be computed as

$$F_{\mathbf{Y}}(y) = F_{\mathbf{X}}(x) = F_{\mathbf{X}}(g^{-1}(y))$$

- (2) The p.d.f. of \mathbf{Y} can be computed as

$$f_{\mathbf{Y}}(y) = F'_{\mathbf{Y}}(y) = \frac{d}{dy} F_{\mathbf{X}}(g^{-1}(y))$$

- (3) The expected value $\mathbb{E}\mathbf{Y}$ can be computed in two different ways as

$$\mathbb{E}\mathbf{Y} = \int_{\min(\mathbf{Y})}^{\max(\mathbf{Y})} y f_{\mathbf{Y}}(y) dy = \int_{\min(\mathbf{X})}^{\max(\mathbf{X})} g(x) f_{\mathbf{X}}(x) dx$$

- (4) To compute $\mathbf{Var}(\mathbf{Y})$, use

$$\mathbb{E}\mathbf{Y}^2 = \int_{\min(\mathbf{Y})}^{\max(\mathbf{Y})} y^2 f_{\mathbf{Y}}(y) dy = \int_{\min(\mathbf{X})}^{\max(\mathbf{X})} (g(x))^2 f_{\mathbf{X}}(x) dx$$

and then

$$\mathbf{Var}(\mathbf{Y}) = \mathbb{E}\mathbf{Y}^2 - (\mathbb{E}\mathbf{Y})^2$$

- *If g is a monotone decreasing function*, then some things are reversed

$$\min(\mathbf{Y}) = g(\max(\mathbf{X})) \leq \mathbf{Y} \leq \max(\mathbf{Y}) = g(\min(\mathbf{X}))$$

$$F_{\mathbf{Y}}(y) = 1 - F_{\mathbf{X}}(x) = 1 - F_{\mathbf{X}}(g^{-1}(y))$$

- *If g is neither monotone decreasing nor monotone increasing, then we have to consider cases.*
